LOCAL-ONLY · OPEN SOURCE · MY OWN MODEL

I built a SOC co-pilot that runs entirely on my laptop.

It reads Windows, Linux and web logs, finds the few events that matter, and cites the exact log line behind every claim.

THE PROBLEM

The logs you most need help with are the ones you can't paste into a chatbot.

10k

Thousands of lines, a handful that matter

Cron chatter and service restarts bury the one 4769 that says someone is roasting your service accounts.

!

Logs are sensitive

Usernames, hosts, internal IPs, command lines. They shouldn't leave the network, let alone go to a cloud LLM.

?

AI sounds sure even when it's wrong

A confident summary is worthless to an analyst unless every claim can be checked against the evidence.

So: keep everything local, and make the AI show its evidence.

HOW IT WORKS

From raw logs to a cited answer, all on one machine

01

Collect

Windows Event Log, exported .evtx and Prefetch folders (read natively on Linux and macOS), journald / syslog, web and app logs.

02

Group

Thousands of lines become a few hundred patterns. Every event keeps its exact position in the original file.

03

Score

~65 detection rules, your Sigma rules, attacker-tool signatures, bursts, and "first time on this host".

04

AI triage

My fine-tuned model reviews each pattern: how much it matters, why, and what to do.

05

Evidence

Summary, timeline, ATT&CK, indicators and a report, every claim linked to the line it came from.

EXAMPLE CASE · THE BUNDLED WINDOWS SAMPLE

A break-in in one Security log. One answer, with receipts.

KEY FINDING

HIGH LSASS memory dump T1003.001

WHEN	2026-11-05 09:11:40 UTC [E2]
WHO	mreyes on WS-FIN07
HOW	rundll32 + comsvcs.dll, MiniDump
AFTER	5 failed logons from 198.51.100.23
THEN	new admin svc_backup, log cleared

THE RECORD BEHIND IT · ONE CLICK FROM THE FINDING

09:09:15Z [4688] New process: powershell.exe -nop -w hidden -enc SQBFAFgA… …

09:11:40Z [4688] A new process has been created. Subject: **mreyes** Process: rundll32.exe Command Line: rundll32.exe C:\Windows\System32**comsvcs.dll**, **MiniDump 664** C:\Users\Public**l.dmp** full

09:13:05Z [4688] New process: net user svc_backup … /add …

TRUST

Fluent isn't the same as right. Three guardrails:

E3

Every claim is cited

The summary and every answer cite numbered log lines. One click opens the exact record in the original file.

✓

Claims are verified

If the model names a tool that doesn't literally appear in the log, it's dropped. It can't invent evidence.

96

Known-answer tests gate every change

Five investigations with known answers, including a healthy machine that must stay quiet, run on every change to rules, prompts or the model.

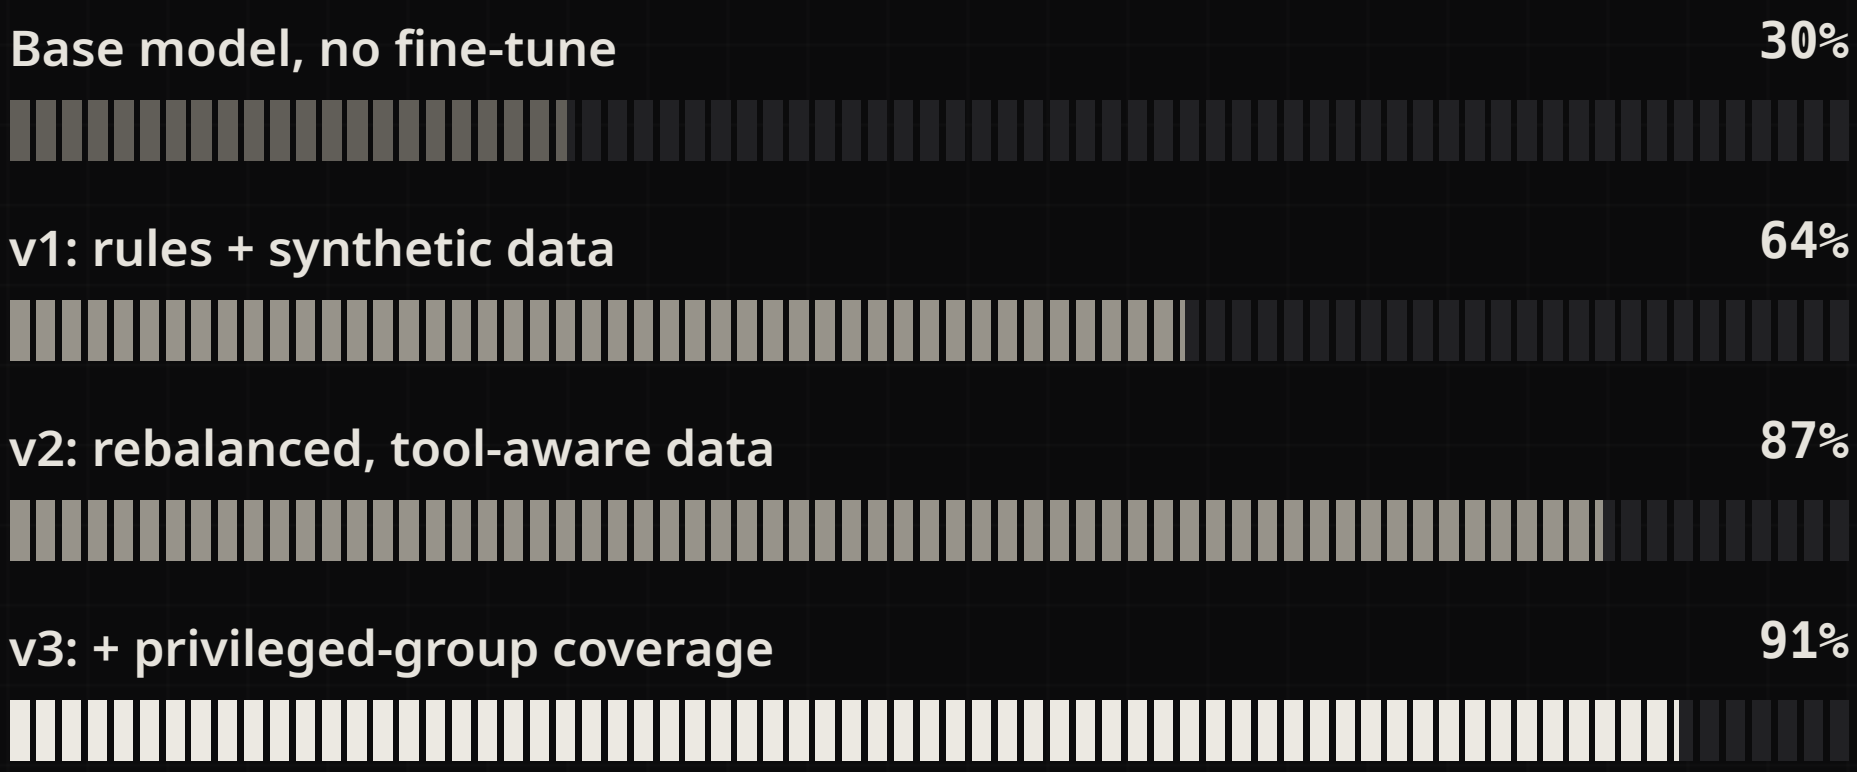

> They already caught a routine LAN login mapped to an ATT&CK technique, a model suggesting "stop sshd" on a machine reached over SSH, and a scan bug that silently overwrote results.

THE MODEL

My own model, fine-tuned on one laptop GPU

4B	8 GB	0
Qwen3-4B base, QLoRA adapter	one laptop GPU, 43 min to train	bytes sent to the cloud

TRIAGE ACCURACY ON HELD-OUT LOGS (EXACT IMPORTANCE)

> New versions only go live if they beat the current one on held-out data and on the known-answer cases. Co-pilot checks: v1 93/96 → v2 95/96 → v3 95/96.

FOR ANALYSTS AND FOR PEOPLE LEARNING

What else it does

LEARN

Explain this event

Field by field: logon types, status codes, what normal looks like, plus the native command to check it yourself.

HUNT

Attacker tools

Mimikatz, LinPEAS, reverse shells, certutil downloads, LSASS dumps, scanners. Each use links to its line.

MAP

ATT&CK by tactic

Evidence only: a routine logon is not "Valid Accounts".

PIVOT

Indicators

IPs, domains, hashes, users with exact counts, pivoted across every past case.

DETECT

Sigma rules

Drop in community rules; unsupported ones are skipped, never half-applied.

REPORT

Timeline & report

One timeline across all logs; a PDF report with every citation resolved to file:line.

TRY IT

No install. No internet. No account.

Unzip, double-click, and the dashboard opens with example investigations ready to explore. The AI runs inside the app.

Windows	`.exe · x64`
macOS	`Apple Silicon · Intel`
Linux	`x64`

What should it catch next?

Tell me in the comments.
